

Week - 3rd, chapter 2

Determinants

Minors and Co-factors: If A is the square matrix

Then the minor of a_{ij} is denoted by M_{ij} .

The number $(-1)^{i+j} M_{ij}$ is denoted by C_{ij} is called the co-factor of entry a_{ij} .

$$Q_1 \text{ Find the minors and cofactor } A = \begin{bmatrix} 3 & 1 & -4 \\ 2 & 5 & 6 \\ 1 & 4 & 8 \end{bmatrix}$$

$$\text{Sohi: The minor of } a_{11} \text{ is } M_{11} = \begin{vmatrix} 5 & 6 \\ 4 & 8 \end{vmatrix} = 16$$

The co-factor of a_{11} is

$$\begin{aligned} C_{11} &= (-1)^{1+1} M_{11} \\ &= (-1)^2 \times 16 \\ &= 16 \end{aligned}$$

Similarly, the minor of a_{12}

$$\text{Ans: } M_{12} = \begin{vmatrix} 2 & 6 \\ 1 & 8 \end{vmatrix} = 16 - 6 = 10$$

The co-factor of a_{12} is

$$\begin{aligned} C_{12} &= (-1)^{1+2} M_{12} = \\ &= (-1)^3 \times 10 \\ &= -10 \end{aligned}$$

Similarly, the minor of a_{22} is

$$M_{22} = \begin{vmatrix} 3 & -4 \\ 1 & 6 \end{vmatrix} = 26$$

$$\text{co-factor of } a_{22} \text{ is } C_{22} = (-1)^{2+2} M_{22} = -M_{22} = -26 //$$

Cofactor expansion Along Row or Column wise

Or find the determinant by cofactor expansion along ~~the~~ first Row
then first column.

$$A = \begin{vmatrix} 3 & 1 & 0 \\ -2 & -4 & 3 \\ 5 & 4 & -2 \end{vmatrix}$$

Soh: By Row side

$$(a) \quad \det(A) = 3 \begin{vmatrix} -4 & 3 \\ 4 & -2 \end{vmatrix} - 1 \begin{vmatrix} -2 & 3 \\ 5 & -2 \end{vmatrix} + 0 \begin{vmatrix} -2 & -4 \\ 5 & 4 \end{vmatrix}$$

$$= 3(-4) - (1)(-11) + 0 =$$

$$= -1$$

(b) By column side

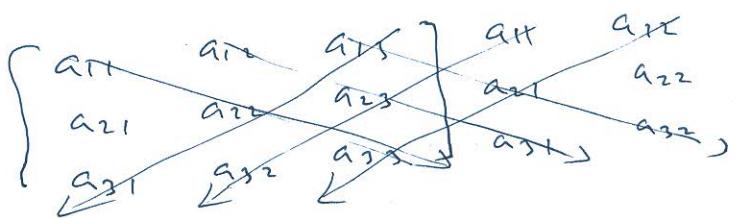

$$= 3 \begin{vmatrix} -4 & 3 \\ 4 & -2 \end{vmatrix} - (-2) \begin{vmatrix} 1 & 0 \\ 4 & -2 \end{vmatrix} + 5 \begin{vmatrix} 1 & 0 \\ -4 & 3 \end{vmatrix}$$

$$= 3(-4) - (-2)(-2) + 5(3)$$

$$= -11$$

Technique To evaluate 2×2 or 3×3 determinants.

$$\begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{bmatrix}$$

$$= a_{11} \cdot a_{22} a_{33} + a_{12} a_{23} a_{31} + a_{13} a_{21} a_{32} - a_{11} a_{23} a_{32} - a_{13} a_{22} a_{31}$$

$$(c) \text{ Calculate } A = \begin{vmatrix} 1 & 5 & -3 \\ 1 & 0 & 2 \\ 3 & -1 & 2 \end{vmatrix}$$

Soh: we can write

$$\begin{vmatrix} 1 & 5 & -3 & 1 & 5 \\ 1 & 0 & 2 & -1 & 0 \\ 3 & -1 & 2 & 3 & -1 \end{vmatrix}$$

Theorem 2.2.5: If A is a square matrix with two proportional rows or two proportional columns, then $\det(A) = 0$ (2)

for ex

$$\begin{vmatrix} 1 & 3 & -2 & 4 \\ 2 & 6 & -4 & 8 \\ 3 & 9 & 1 & 5 \\ 1 & 1 & 4 & 8 \end{vmatrix}$$

\therefore Second Row is 2 times the first Row
if we $R_2 \rightarrow R_2 - 2R_1$, we get $R_2 = 0 \therefore \det A = 0$

Evaluate the determinant by Row Reduction

In this we convert the determinant into upper triangular matrix using Row operation.

Q. Evaluate $\det(A) =$

$$\begin{vmatrix} 0 & 1 & 5 \\ 3 & -6 & 9 \\ 2 & 6 & 1 \end{vmatrix} \quad R_2 \leftrightarrow R_1$$

Soh:

$$\det(A) = - \begin{vmatrix} 3 & -6 & 9 \\ 0 & 1 & 5 \\ 2 & 6 & 1 \end{vmatrix} \quad R_1 \text{ take common } 3$$

$$= -3 \begin{vmatrix} 1 & -2 & 3 \\ 0 & 1 & 5 \\ 2 & 6 & 1 \end{vmatrix} \quad R_3 \rightarrow R_3 - 2R_1$$

$$= -3 \begin{vmatrix} 1 & -2 & 3 \\ 0 & 1 & 5 \\ 0 & 10 & -5 \end{vmatrix} \quad R_3 \rightarrow R_3 - 10R_2$$

$$= -3 \begin{vmatrix} 1 & -2 & 3 \\ 0 & 1 & 5 \\ 0 & 0 & -55 \end{vmatrix} \quad R_3 \text{ common } (-55)$$

$$(-3)(-55) \begin{vmatrix} 1 & -2 & 3 \end{vmatrix}$$

$$= (-3)(-55)(1) \\ = 165$$

Theorem 2.3.3 A square matrix A is invertible iff

$$\det(A) \neq 0$$

Q. check whether A is invertible or not $A = \begin{bmatrix} 1 & 2 & 3 \\ 1 & 0 & 1 \\ 2 & 4 & 6 \end{bmatrix}$

Soln: R_1 and R_3 are proportional.

$$\therefore \det(A) = 0$$

$\therefore \det(A)$ is not invertible

Theorem: If A and B are square matrices of the same size.

$$\text{Then } \det(AB) = \det(A)\det(B)$$

Q. consider $A = \begin{bmatrix} 3 & 1 \\ 2 & 1 \end{bmatrix}, B = \begin{bmatrix} -1 & 3 \\ 5 & 0 \end{bmatrix}$,

$$AB = \begin{bmatrix} 2 & 17 \\ 3 & 14 \end{bmatrix}$$

Soln: $\det(A) = 3 - 2 = 1$

$$\det(B) = -3 - 15 = -18$$

$$\det(AB) = 28 - 51 = -23$$

$$\therefore \det(AB) = \det(A)\det(B)$$

$$-23 = 1 \times (-23) //$$

Cramers Rule : If $Ax = b$ is a system of n linear equations in n unknowns such that $\det(A) \neq 0$, then the system has a unique solution, this solution is (3)

$$x_1 = \frac{\det(A_1)}{\det(A)}, x_2 = \frac{\det(A_2)}{\det(A)}, \dots, x_n = \frac{\det(A_n)}{\det(A)}$$

where $A_1 = \begin{vmatrix} b_1 & a_{11} & a_{12} \\ b_2 & a_{21} & a_{22} \\ b_3 & a_{31} & a_{32} \end{vmatrix}, A_2 = \begin{vmatrix} a_{11} & b_1 & a_{13} \\ a_{21} & b_2 & a_{23} \\ a_{31} & b_3 & a_{33} \end{vmatrix}$

$$A_3 = \begin{vmatrix} a_{11} & a_{12} & b_1 \\ a_{21} & a_{22} & b_2 \\ a_{31} & a_{32} & b_3 \end{vmatrix}$$

Q. Using Cramers Rule to solve

$$\begin{aligned} x_1 + 2x_2 + 2x_3 &= 6 \\ -3x_1 + 4x_2 + 6x_3 &= 30 \\ -x_1 - 2x_2 + 3x_3 &= 8 \end{aligned}$$

Soh:
Given $A = \begin{bmatrix} 1 & 0 & 2 \\ -3 & 4 & 6 \\ -1 & -2 & 3 \end{bmatrix}$

$$A_1 = \begin{bmatrix} 6 & 0 & 2 \\ 30 & 4 & 6 \\ 8 & -2 & 3 \end{bmatrix}, A_2 = \begin{bmatrix} 1 & 6 & 2 \\ -3 & 30 & 6 \\ -1 & 8 & 3 \end{bmatrix}$$

$$A_3 = \begin{bmatrix} 1 & 0 & 6 \\ -3 & 4 & 30 \\ -1 & -2 & 8 \end{bmatrix}$$

Now $\det(A_1) = -40, \det(A) = 44, \det(A_2) = 72$
 $\det(A_3) = 152$

Now find

$$x_1 = \frac{\det(A_1)}{\det(A)} = -\frac{46}{44} = \frac{-10}{11}$$

$$x_2 = \frac{\det(A_2)}{\det(A)} = \frac{72}{44} = \frac{18}{11}$$

$$x_3 = \frac{\det(A_3)}{\det(A)} = \frac{152}{44} = \frac{38}{11}$$

Q If $A = \begin{pmatrix} 5 & -2 & 1 \\ 0 & 3 & -1 \\ 2 & 0 & 7 \end{pmatrix}$ and $|A| = 103$. Evaluate the determinants of the following matrices.

$$B = \begin{pmatrix} 5 & -2 & 1 \\ 0 & 6 & -2 \\ 2 & 0 & 7 \end{pmatrix}, C = \begin{pmatrix} 5 & -2 & 1 \\ 2 & 0 & 7 \\ 0 & 3 & -1 \end{pmatrix}, D = \begin{pmatrix} 5 & -2 & 1 \\ 0 & 3 & -1 \\ 12 & -4 & 9 \end{pmatrix}$$

Soh: Theorem 2.2.3: Let A be an $n \times n$ matrix

- If B is the matrix that results when a single row or single column of A is multiplied by a scalar k , then $\det(B) = k \det(A)$
- If B is the matrix that results when two rows or two columns of A are interchanged, then $\det(B) = -\det(A)$
- If B is the matrix that results when a multiple of one row of A is added to another row or when a multiple of one column is added to another column, then $\det(B) = \det(A)$

Soh: (B) B is the matrix resulted when the second row of A is multiplied by 2. Now using (a) theorem (a)

$$|B| = 2|A| = 2 \cdot 103 = 206$$

(C) C is the matrix resulted when the second and third rows of A are interchanged. Now using theorem (b)

$$|C| = -|A| = -103$$

(D) D is the matrix resulted when the first row of A multiplied by 2 and added to the third row of A . using theorem (c)

$$|D| = |A| = 103$$

$$\begin{aligned} 3x + 2y + z &= 11 \\ x - 5y + z &= -5 \end{aligned}$$

Soln:

$$A = \begin{bmatrix} 1 & 2 & 3 \\ 3 & 2 & 1 \\ 1 & -5 & 1 \end{bmatrix}, b = \begin{bmatrix} 17 \\ 11 \\ -8 \end{bmatrix}, |A| = -48$$

$$A_1 = \begin{bmatrix} 17 & 2 & 3 \\ 11 & 2 & 1 \\ -5 & -5 & 1 \end{bmatrix}, A_2 = \begin{bmatrix} 1 & 17 & 3 \\ 3 & 11 & 1 \\ 1 & -5 & 1 \end{bmatrix}$$

$$A_3 = \begin{bmatrix} 1 & 2 & 17 \\ 3 & 2 & 11 \\ 1 & -5 & -5 \end{bmatrix}$$

Now we find that

$$|A_1| = -48, |A_2| = -96, |A_3| = -192$$

Thus

$$x = \frac{|A_1|}{|A|} = \frac{-48}{-48} = 1$$

$$y = \frac{|A_2|}{|A|} = \frac{-96}{-48} = 2$$

$$z = \frac{|A_3|}{|A|} = \frac{-192}{-48} = 4$$
